I am studying the source organization and do not currently have access to a BSD machine I can rebuild to include kernel debugging.

I was wondering if someone could explain (or illustrate) the back trace (call stack) of a call from `int open(const char*, int)` all the way through to the UFS layer.

I am looking at the source code and am making progress, but it is long and tedious work without a compiling and step-able code.

Thanks for any help.

Oh, and if this isn't a appropriate request for this list please tell me.

Woolie
