Hi!

I have some troubles with my notebook and any version of FreeBSD (starting with 6 since my sata controller wasn't supported earlier). It looks like as it would end up in a deadlock which means i have no access to the debugger nor to any other kind of tracing methods. Even with KTR, WITNESS and DIAGNOSTIC enabled in the kernel I get no message what went wrong or what might have caused the trouble. These fullstops always turn up when i compile and install programs (or sometimes during the installation of FreeBSD itself)

Hardware:

Intel Pentium-M 760 (Centrino, 2GHz)  
VIA VT 6421 SATA Controller  
80GB Samsung SATA HD

I guess one of those parts creates the trouble, but I have no idea how to trace it...

Is there a way to run the whole thing in some kind of debugger?  
Or is there a different way to locate the problem?

Thank's in advance and a Happy New Year,
