Hi,

I don't want to re-invent the wheel and am looking for a web and rrd based monitoring program for FreeBSD.

Doesn't need to be an "enterprise" system, its only for my home machine.

I want to keep track over time, how my system is loaded over time and "releases".

Basically I want to be able to track most of vmstat output. Additionally network load and something like temperature.

Is there something like this available that does this already in a nicely manner with good overview ... ?

I remember, that I found such a beast, but I can't remember the name of the software. I looked today at several ports but didnt find something like that.

Something like cacti, but maybe already more pre-configured for system performance monitoring.
