Following an unrelated discussion about "interface grouping" in OpenBSD, I'd like to know if there are any known or planned implementations of LACP (802.3ad) interface teaming in FreeBSD?

FreeBSD currently has etherchannel support, but to my knowledge that will only work for a link to a single switch and not provide the possibility of having layer 2 resilience with paths to 2 switches in the same network.

Any thoughts on this?

NetBSD has an implementation which would be a good starting place for anyone looking into this.
