Having just migrated a server from 4.10-STABLE to 6.1-STABLE, I'm curious about some kernel messages in dmesg that I hadn't seen before:

```
asr0: [GIANT-LOCKED] (adaptec RAID adapter)
uhci0: [GIANT-LOCKED] (USB driver)
atkbd0: [GIANT-LOCKED] (keyboard driver)
```

I'm running SMP with 2 CPUs...a quick google shows that some people think it may be cause for concern but others do not. Is it?

Then there's this:

```
acpi0: <PTLTD RSDT> on motherboard
acpi0: Power Button (fixed)
acpi: bad write to port 0x070 (8), val 0x43
acpi: bad read from port 0x071 (8)
```

That driver isn't in my kernel which is derived from GENERIC; I found info on it in PAE:

```
# Compile acpi in statically since the module isn't built properly. Most
# machines which support large amounts of memory require acpi.
device acpi
```

I only have 1GB of RAM in this server, so can I simply ignore this?
