This is a newly installed stable machine, cvsupped and rebuilt this weekend. I have installed postfix with amavisd-new and clamav. They are all set for startup in /etc/rc.conf and sendmail is appropriately marked out, I have set up quite a few of these in the recent past. However neither amavis, clamav or postfix start automatically, they can all be started manually. I have turned on rc_debug, but they are not mentioned at all, their scripts are all in /usr/local/etc/rc.d. The only script mentioned in the debug output is fetchmail, which is not enabled in the rc.conf. They are all freshly install from ports. Where can I start looking to get this running?

Output of "rcorder /etc/rc.d/* /usr/local/etc/rc.d/*" would be where I'd look next. Probably save it to a file (normal stdout redirection).

Peace,
david
