Thanks to all those that responded!

So many replies, seems the advantages far outweigh any performance deficit especially in our environment.

I included this reply as it was by far my favourite (Credit to Michael Horton!)

=====

no calls to fsck disks during reboots will make you look unimportant.

no rescue beeps in the night that get you out of awkward situations.

no ignoring the boss with "i've got to fix the server!".

but this can be remedied with cron and other programs.

=====

Cheers all!

Scott

Original message:

Hi all,

Looking at implementing UFS Logging on our servers by adding the logging entry in /etc/vfstab, the servers can have a habit of unscheduled poweroffs and with potentially huge chunks of data attached logging enabled could give huge benefits in recovering a system like this.

Are there any disadvantages to using it?
